(Received May 19, 2006)

Summary Prunes are the dried fruits of certain cultivars of Prunus domestica L., and are recognized as a health food. The separated ethanol fraction from concentrated prune juice by DIAION HP-20 (PE) was investigated for cytotoxic effects on two different cancer cell lines in vitro. PE dose-dependently reduced the viable cell number of Caco-2, KATO III, but does not reduce the viable cell number of human normal colon fibroblast cells (CCD-18Co) used as a normal cell model. PE treatment for 24 h led to apoptotic changes in Caco-2 such as cell shrinkage and blebbed surfaces due to the convolutions of nuclear and plasma membranes and chromatin condensation, but this was not observed in CCD-18Co. PE induced nucleosomal DNA fragmentation typical of apoptosis in Caco-2 after 24 h of treatment. These results show that PE induced apoptosis in Caco-2. Furthermore, by Caco-2 treatment with H2O2 chelator catalase and Ca2+-chelator BAPTA/AM, the PE-induced cytotoxic pathway was completely blocked, and the viable cell number of Caco-2 was not affected.

Key Words prunes (Prunus domestica L.), apoptosis, Caco-2, KATO III, CCD-18Co

Prunes are the dried fruit of certain cultivars of Prunus domestica L., which belongs to the Rosaceae family that originated in the Caucasus region of western Asia. Prunes have been medicinally in India in combination with other drugs for the treatment of leukorrhea, irregular menstruation, and debility following miscarriage (1). In recent years, prunes are eaten in the dry state, as juice, and as concentrated prune juice. They are recognized as a health food (2).

In previous studies concerning prunes, it was reported that low-density lipoprotein (LDL) cholesterol in human plasma (3), as well as plasma and liver lipids in rats (4), were lowered by a high intake of the dietary fiber in plums. In addition, prune consumption has been seen to induce bone formation in postmenopausal women (5), and improve bone mineral density loss (6, 7) and ovariectomy-induced hypercholesterolemia (8) in rats. Thus, these reports indicate that prunes can improve various diseases, but there are few reports concerning cancer. Many reports have shown that polyphenols can control cancer (9, 10). Since several polyphenols such as chlorogenic acid are contained in prunes, they are expected to have an effect on controlling cancer.

The separated ethanol fraction from concentrated prune juice by DIAION HP-20 (PE) was investigated for cytotoxic effects on two different cancer cell lines in vitro. PE was found to be effective in inhibiting Caco-2 human colon carcinoma and KATO III human stomach carcinoma in vitro. PE reduced the viable cell number and induced apoptosis in Caco-2. These results suggest that the growth inhibitory and apoptosis-inducing effects of PE in cancer cells are crucial pathways for cancer prevention.

Materials and Methods

Fractionation of concentrated prune juice. Concentrated prune juice, MIKI Prune EXTRACT, was supplied by MIKI Foods Co., Ltd. MIKI Prune EXTRACT was applied to a DIAION HP-20 and partitioned between ethanol and water. The ethanol soluble part was evaporated under reduced pressure. About 25 g of PE was obtained from 800 g of MIKI Prune EXTRACT.

Cells and cell culture. Caco-2 human colon carcinoma and CCD-18Co normal human colon fibroblast were maintained in Eagle’s MEM supplemented with 10% heat-inactivated fetal calf serum (FCS) and 1% nonessential amino acid solution. KATO III human stomach carcinoma was maintained in a combination medium of Eagle’s MEM + RPMI1640 supplemented with 10% heat-inactivated FCS. All cell lines were cultured at 37°C in a humidified 5% CO2 atmosphere.

Cell viability assay. The effects of PE on cellular viability were determined by a 2-(2-methoxy-4-nitropheno-nyl)-3-(4-nitrophenyl)-5-(2,4-disulfolphenyl)-2H-tetrazolium (WST-8) assay using a commercial kit (Tetra Color ONE, Seikagaku Corporation). Briefly, 1 × 104 cells in 1 mL medium were plated on a 24-well microplate and incubated for 48 h for attachment. The medium was then replaced with the same amount of new medium with several concentrations of PE added. After incuba-
tion, it was replaced with new medium supplemented with 10% WST-8. After 1 h of incubation, the formation of formazan was determined photometrically at 450 nm with a microplate reader. The results are shown as the ratio of figures tested to the untreated control, and all analyses were performed on sets of four wells.

DNA extraction and agarose gel electrophoresis. DNA fragmentation was determined using a commercial kit (Quick Apoptotic DNA Ladder Detection Kit, BioVision). Briefly, cells (approximately 5 × 10^5 cells) were lysed in 40 μL of Tris-EDTA lysis buffer, incubated with a 5 μL Enzyme A (RNase) solution at 37°C for 10 min, and then incubated with a 5 μL Enzyme B (Protease K) solution at 50°C for 30 min. DNA was then precipitated with isopropanol and resuspended in DNA suspension buffer. DNA were electrophoresed in Tris-borate buffer on 1% agarose gel and stained with ethidium bromide.

Cell morphology. To assess morphological changes, cells were treated with the PE concentrations mentioned above. After treatment, photographs were taken using a phase-contrast microscope.

Results and Discussion

Initially, the effects of PE on cell viability were examined. PE was added to a medium supplemented with 0.3% FCS of Caco-2, KATO III and CCD-18Co, and incubated for 24 h. PE dose-dependently reduced the viable cell number of Caco-2 and KATO III, but did not reduce the viable cell number of CCD-18Co (Fig. 1A). In the medium supplemented with 10% FCS, PE dose-dependently inhibited the proliferation of Caco-2 following 24 and 48 h of incubation (Fig. 1B).

Figure 2 shows the apoptosis-inducing effects of PE on Caco-2. Treatment of Caco-2 with PE had a remarkable effect on the cell morphology. The 0.25 mg/mL PE treatment for 24 h led to apoptotic changes such as cell shrinkage and blebbed surfaces due to the convolutions.
of nuclear and plasma membranes and chromatin condensation, but this was not observed in CCD-18Co (Fig. 2A). PE induced nucleosomal DNA fragmentation typical of apoptosis in Caco-2 after 24 h of treatment (Fig. 2B). These results show that PE induced apoptosis in Caco-2. The main chemical compound contained in prunes is chlorogenic acid, which accounts for about 10% of PE (11). There is a report that chlorogenic acid produces large DNA fragments and nuclear condensation, and activates caspase in human oral tumor cells (12). However, a number of reports have demonstrated that chlorogenic acid has little modulating effect on cell viability and the apoptosis of cancer cells in vitro (10, 13). In fact, we have data that 1 mM chlorogenic acid has no effect on the viability of Caco-2 (data not shown). These data might indicate an important role together with other chemical compounds in controlling cancer cell proliferation in vivo also, possibly by synergistic effects.

Figure 3 shows the effects of inhibitors on PE-induced cell death in Caco-2. PE dose-dependently reduced the viable cell number of Caco-2. When Caco-2 was treated with H2O2 chelator catalase (3,000 U/mL), the PE-induced cytotoxic pathway was completely blocked, and the viable cell number of Caco-2 was not affected (Fig. 3). BAPTA/AM (250 μM), which penetrates the cell subsequent to hydrolysis to BAPTA, which serves as an intracellular Ca2+ chelator, also completely abolished the reduction in the viable cell number of Caco-2 (Fig. 3). Disruption of cellular reactive oxygen species (ROS) and Ca2+ homeostasis has been proposed as a critical event in both apoptosis and necrosis (14). The involvement of increased Ca2+ was reported in cells undergoing apoptosis in many different settings. Similarly, ROS is related to apoptosis. Recently, many H2O2-sensitive transcription factors (such as AP-1, NF-κB), which are related to apoptosis, have been reported (15, 16). Further study is required to test factors inducing apoptosis.

In summary, the effects of PE in cell viability and apoptosis were evaluated. PE had apoptosis-inducing effects, some of which involved cellular H2O2 and Ca2+. These results suggest that PE might exert cancer-preventive action through apoptosis- and/or cell proliferation-dependent mechanisms.
